Warp Stabilizer increases the number of control points and is not compatible with the Motion Blur effect. Digital video stabilization By using video stabilization, the shaky footage is moved around to create a stable image. Like traditional image stabilizer, it is also used to remove unwanted motion blur from a video or still image. With computer imaging and movie production software, it is possible to automate some of the work required by a traditional camera stabilizer. In the field of cinematography, there are two main types of stabilizers. Hardware This kind of stabilizer is part of the camera, used to counter shake or vibration caused by the camera operator. Hardware stabilizers are a part of the camera setup and have an analog and/or digital connection to the camera body. Examples of this kind of stabilizer are the Focus XT, the AimPoint X, the Steadicam, the Steadicam Shotgun, the Monsoon MTS Mini, the Phantom Flex, the Cambridge RC10, the Zenmuse H3, the Zacuto Video Go and the Voom. Some of the aforementioned camera stabilizers are standalone stabilizers, which are not part of the camera. Instead, they attach to the camera body. To the right is a list of some of the well-known stabilizers. Software In video editing, computer imaging and movie production software, it is possible to create digital stabilizer effects. The stabilizer tool usually has a timeline with frames of the video being able to be moved back and forth over time, which moves the sequence of the video that is shown in real time. In this kind of stabilizer, the image stabilization is done on a frame by frame basis. Some software also allows for the stabilizer to be removed on certain frames and/or for the image to be stabilized at specific points. See also Motion blur Image stabilization References External links Category:Image processingThe present invention relates to a method and apparatus for measurement of the performance of a rotating magnetic field imager (MRI), and more particularly to a method and apparatus for measuring the properties of a gradient field in an MRI using a model of the gradient field. In magnetic resonance imaging, the body of a patient is placed in a strong magnetic field (B0) in which the patient's nuclear spins (e.g., protons in water molecules) align with the applied magnetic field.
